What do we seek in a hierarchical clustering?

Justin Eldridge, Mikhail Belkin, Yusu Wang The Ohio State University

May 13, 2015

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

The goal of clustering: Identify structure in data by grouping it into *clusters*

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

The goal of clustering: Identify structure in data by grouping it into *clusters*

Assumption: data is generated by some source with structure. This structure is what we *actually* want to recover.

Theory of clustering

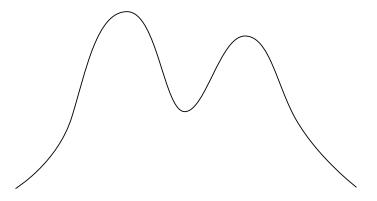

Given a data source (i.e., a density):

- How is a cluster defined?
- What cluster structure do we wish to recover?

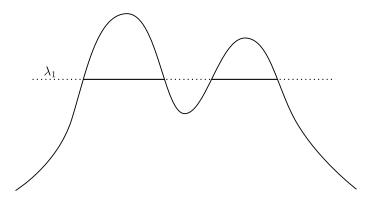

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

How do we define a cluster of a density f?

A region of high density: Hartigan (1981), Wishart (1969)...

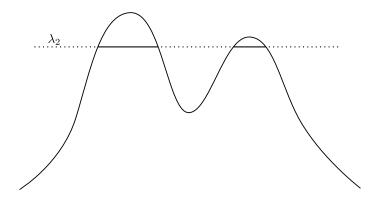

Connected components of $\{f \geq \lambda_1\}$?

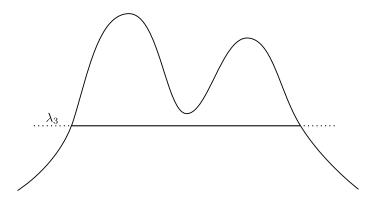

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

Connected components of $\{f \ge \lambda_2\}$?

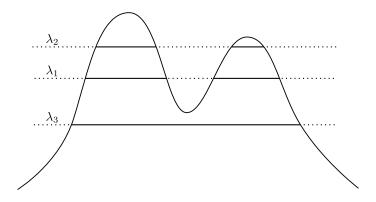

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

Connected components of $\{f \geq \lambda_3\}$?

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

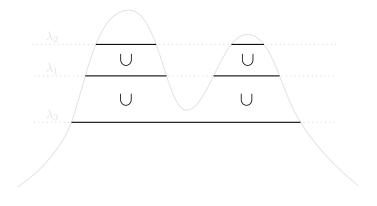

A cluster is a connected component of $\{f \ge \lambda\}$ for any $\lambda > 0$.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

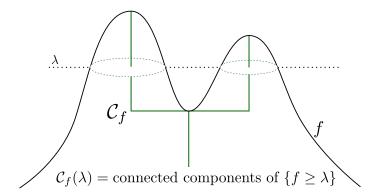

A hierarchy of clusters

Clusters from higher levels nest within clusters from lower levels.

The density cluster tree

This gives rise to a tree structure called the *density cluster tree*.

Given a density:

How is a cluster defined?

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Given a density:

- How is a cluster defined?
 - A region of high density.

Given a density:

- How is a cluster defined?
 - A region of high density.
 - ► Formally: A connected component of a superlevel set.

To answer this, Hartigan (1981) defined notion of consistency:

- A density f supported on \mathcal{X}
- A sample $X_n \sim f$
- ► A method producing an estimate Ĉ_{f,n} of the density cluster tree

A method is *Hartigan consistent* if as $n \to \infty$, any two disjoint clusters in the density cluster tree of f are kept separate by $\hat{C}_{f,n}$

Hartigan consistency

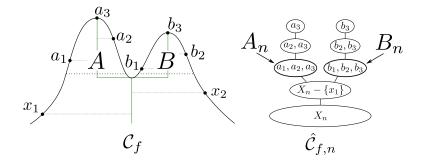

Notation: For any set A ⊂ X, let A_n denote the smallest cluster of Ĉ_{f,n} containing A ∩ X_n

イロト イポト イヨト イヨト

э

Hartigan consistency

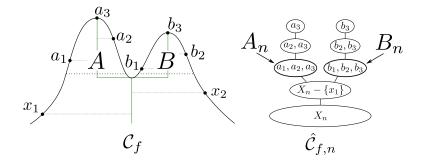

Notation: For any set A ⊂ X, let A_n denote the smallest cluster of Ĉ_{f,n} containing A ∩ X_n

イロト イポト イヨト イヨト

э

► A_n is the "tightest" empirical cluster recovering A

Hartigan consistency

- Notation: For any set A ⊂ X, let A_n denote the smallest cluster of Ĉ_{f,n} containing A ∩ X_n
- ► A_n is the "tightest" empirical cluster recovering A
- Consistency: whenever A and B are different connected components of {f ≥ λ}, Pr(A_n is disjoint from B_n) → 1 as n→∞.

 Hartigan analyzed single linkage, showed that it is not consistent in d > 1

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency is not sufficient
- ▶ We introduce two *new* properties: *minimality* and *separation*

- We show that $minimality + separation \implies$ consistency
- But first we need some definitions...

Cluster tree with height function

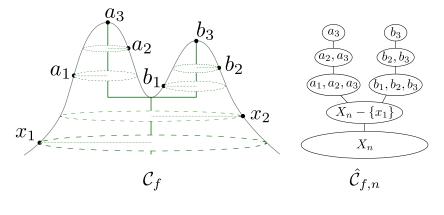

Definition

A cluster tree with a height function is a triple C = (X, C, h), where:

- X is a set of objects,
- C is a cluster tree of X,
- ▶ and $h: X \to \mathbb{R}$ is a height function mapping each point in X to a "height".

We define the height of a cluster $C \in C$ to be the infimal height of any point in the cluster. That is, $h(C) = \inf_{x \in C} h(x)$.

Cluster tree with height function

 $h(\{b_3\}) = f(b_3)$ $h(\{b_2, b_3\}) = f(b_2)$ $h(\{b_1, b_2, b_3\}) = f(b_1)$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Connectedness and separation

Definition

Points x and x' are connected at level λ if there is a cluster C containing both, with h(C) ≥ λ

• Otherwise they are separated at level λ

Connectedness and separation

Definition

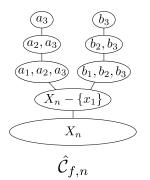

- Points x and x' are connected at level λ if there is a cluster C containing both, with h(C) ≥ λ
- Otherwise they are separated at level λ
- A set S is connected at level λ if any two points s, s' ∈ S are connected at level λ

Sets S and S' are separated at level λ if for any s ∈ S, s' ∈ S', s and s' are separated at level λ

Merge height

Definition

The merge height of two points x and x', written $m_{\rm C}(x, x')$, is the height of the smallest cluster containing both.

$$m_{\hat{C}_{f,n}}(a_3, b_3) = h(X_n - \{x_1\})$$
$$m_{\hat{C}_{f,n}}(a_2, a_3) = h(\{a_2, a_3\})$$

Non-minimality revisited

Recall:

Definition (δ -non-minimality)

- Let A be a connected component of $\{f \ge \lambda\}$.
- Let A_n be the smallest cluster of $\hat{\mathcal{C}}_{f,n}$ containing all of $A \cap X_n$

• We say that A_n is δ -non-minimal if $\min_{x \in A_n} f(x) < \lambda - \delta$.

In other words:

- We say that A_n is δ -non-minimal if $h(A_n) < \lambda \delta$
- That is, $A \cap X_n$ is not connected at level $\lambda \delta$

Non-minimality revisited

Recall:

Definition (δ -non-minimality)

- Let A be a connected component of $\{f \ge \lambda\}$.
- Let A_n be the smallest cluster of $\hat{C}_{f,n}$ containing all of $A \cap X_n$
- We say that A_n is δ -non-minimal if $\min_{x \in A_n} f(x) < \lambda \delta$.

In other words:

- We say that A_n is δ -non-minimal if $h(A_n) < \lambda \delta$
- That is, $A \cap X_n$ is not connected at level $\lambda \delta$

We want $A \cap X_n$ to be connected at level $\lambda - \delta$, with δ small.

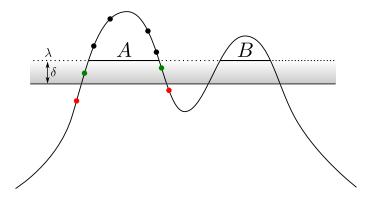

Minimality

Definition (Minimality)

A method ensures *minimality* if given any cluster A of $\{f \ge \lambda\}$, $A \cap X_n$ is connected at level $\lambda - \delta$ in $\hat{C}_{f,n}$ for any $\delta > 0$ as $n \to \infty$ Where:

- f is a density supported on \mathcal{X}
- $X_n \sim f$
- ▶ $\hat{C}_{f,n}$ is an estimate of the true cluster tree, equipped with f as a height function

Minimality

Separation

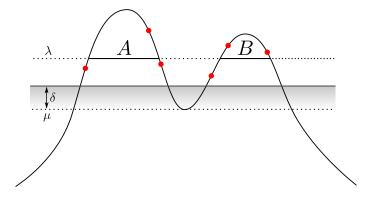

Definition (Separation)

A method ensures separation if when A and B are two disjoint connected components of $\{f \ge \lambda\}$ merging at $\mu = m_{C_f}(A \cup B)$, $A \cap X_n$ and $B \cap X_n$ are separated at level $\mu + \delta$ in $\hat{C}_{f,n}$ for any $\delta > 0$ as $n \to \infty$.

Where:

- f is a density supported on \mathcal{X}
- $X_n \sim f$
- ▶ $\hat{C}_{f,n}$ is an estimate of the true cluster tree, equipped with f as a height function

Separation

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Minimality + separation \implies Hartigan consistency

Theorem

If a hierarchical clustering method ensures both separation and minimality, then it is Hartigan consistent.

Uniform minimality and separation

Definition

We say that $\hat{C}_{f,n}$ ensures uniform minimality if given any $\delta > 0$ there exists an N depending only on δ such that for all $n \ge N$ and all λ , any cluster $A \in \{x \in \mathcal{X} : f(x) \ge \lambda\}$ is connected at level $\lambda - \delta$.

Definition

 $\hat{C}_{f,n}$ is said to ensure *uniform separation* if given any $\delta > 0$ there exists an N depending only on δ such that for all $n \ge N$ and all μ , any two disjoint connected components merging in $\{x \in \mathcal{X} : f(x) \ge \mu\}$ are separated at level $\mu + \delta$.

Uniform minimality and separation

Theorem

If the density f is:

- bounded from above,
- such that {f ≥ λ} contains finitely many connected components for any λ,

then

- minimality => uniform minimality
- ▶ separation ⇒ uniform separation

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Minimality and separation
- 2. How "close" is a clustering to the ideal density cluster tree?
- 3. Do algorithms exist which have these properties/converge to the true density cluster tree?

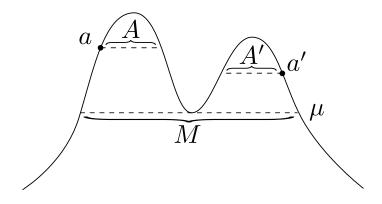

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Minimality and separation
- 2. How "close" is a clustering to the ideal density cluster tree?
- 3. Do algorithms exist which have these properties/converge to the true density cluster tree?

Merge distortion metric

- We have introduced two desirable limit properties: *minimality* and *separation*
- But we may want a quantitative measure of convergence
- We introduce a distance between the true cluster tree and an estimate

Convergence will imply minimality and separation

Merge distortion metric

At what height do a and a' merge in $\hat{C}_{f,n}$?

- *Minimality*: *M* connected at $\mu \delta$, with $\delta \rightarrow 0$
- Separation: A and A' separated at $\mu + \delta$, with $\delta \rightarrow 0$
- Minimality + separation $\implies m_{\hat{C}_{f,n}}(a, a') = \mu \pm \delta$

Merge distortion metric

We define the merge distortion metric as:

$$d(C_f, \hat{C}_{f,n}) = \max_{x, x' \in X_n} |m_{C_f}(x, x') - m_{\hat{C}_{f,n}}(x, x')|.$$

where:

- $X_n \sim f$
- C_f is the true cluster tree of f
- C
 f,n is the estimated cluster tree
- Each tree is equipped with f as height function
- m_{C_f} and $m_{\hat{C}_{f,n}}$ are the merge heights in C_f and $\hat{C}_{f,n}$

Convergence to the density cluster tree

Definition

We say that a sequence of cluster trees $\{\hat{C}_{f,n}\}$ converges to the high density cluster tree C_f of f, written $\hat{C}_{f,n} \rightarrow C_f$, if for any $\varepsilon > 0$ there exists an N such that for all $n \ge N$, $d(\hat{C}_{f,n}, C_f) < \varepsilon$.

Note

Convergence in the merge distortion metric implies that for any two points x and x', $|m_{C_f}(x, x') - m_{\hat{C}_{f,n}}(x, x')| \to 0$ as $n \to \infty$.

Properties of convergence

Theorem $\hat{C}_{f,n} \rightarrow C_f$ implies 1) uniform minimality and 2) uniform separation.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Properties of convergence

Theorem

 $\hat{C}_{f,n} \rightarrow C_f$ implies 1) uniform minimality and 2) uniform separation.

Theorem

If $\hat{C}_{f,n}$ ensures uniform separation and uniform minimality, then $\hat{C}_{f,n} \to C_f$.

Merge distortion metric (general cluster trees)

Definition

Let $C_1 = (X_1, C_1, h_1)$ and $C_2 = (X_2, C_2, h_2)$ be two hierarchical clusterings equipped with height functions. Let $S_1 \subset X_1$ and $S_2 \subset X_2$. Let $\gamma \subset S_1 \times S_2$ be a correspondence between S_1 and S_2 . The distance between C_1 and C_2 with respect to γ is defined as

$$d_{\gamma}(\mathsf{C}_{1},\mathsf{C}_{2}) = \max_{(x_{1},x_{2}),(x_{1}',x_{2}')\in\gamma} |m_{\mathsf{C}_{1}}(x_{1},x_{1}') - m_{\mathsf{C}_{2}}(x_{2},x_{2}')|$$

L_∞ -stability of true cluster tree

Theorem

- Given a density $f : \mathcal{X} \to \mathbb{R}$ and a perturbed density $\tilde{f} : \mathcal{X} \to \mathbb{R}$
- Let C_f and $C_{\tilde{f}}$ be density cluster trees
- Let C_f := (X, C_f, f) and C_{f̃} := (X, C_{f̃}, f̃) be the cluster trees equipped with height functions

Then we have $d(C_f, C_{\tilde{f}}) \leq \|f - \tilde{f}\|_{\infty}$

L_{∞} -stability w.r.t. f

Theorem

Let $C_1 := (\mathcal{X}, \mathcal{C}, f_1)$ and $C_2 := (\mathcal{X}, \mathcal{C}, f_2)$ be two cluster trees with height functions. Then we have $d(C_1, C_2) \le 2 \|f_1 - f_2\|_{\infty}$.

Some implications:

- If f is a consistent density estimate, then true cluster tree of f converges to true cluster tree of f
- Then estimated cluster tree of \hat{f} converges to true cluster tree of f

 This justifies sampling points until distance between consecutive estimated cluster trees is small

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Minimality and separation
- 2. How "close" is a clustering to the ideal density cluster tree?
 Merge distortion metric
- 3. Do algorithms exist which have these properties/converge to the true density cluster tree?

- Do algorithms exist which have these properties?
- Kleinberg makes us nervous...
 - Gave three desirable properties
 - 1. Scale invariance
 - 2. Richness
 - 3. Consistency
 - Showed that no algorithm exists
- But indeed there are. We analyze two:
 - Split tree clustering
 - Robust single linkage (Chaudhuri and Dasgupta, 2010)

Robust single linkage (Chaudhuri and Dasgupta, 2010)

Given a sample X_n of *n* points, and parameters α and *k*:

- 1. For each $x_i \in X_n$, set $r_k(x_i)$ to be the distance from x_i to its kth neighbor.
- 2. As *r* grows from 0 to ∞ :
 - Construct a graph G_r with nodes $\{x_i : r_k(x_i) \le r\}$.
 - Include edge (x_i, x_j) if $||x_i x_j|| \le \alpha r$.
 - The *clusters* at time r are the connected components of G_r .

Robust single linkage (Chaudhuri and Dasgupta, 2010)

Given a sample X_n of *n* points, and parameters α and *k*:

- 1. For each $x_i \in X_n$, set $r_k(x_i)$ to be the distance from x_i to its kth neighbor.
- 2. As *r* grows from 0 to ∞ :
 - Construct a graph G_r with nodes $\{x_i : r_k(x_i) \le r\}$.
 - Include edge (x_i, x_j) if $||x_i x_j|| \le \alpha r$.
 - The *clusters* at time r are the connected components of G_r .

Output is a finite cluster tree.

Convergence of robust single linkage

Robust single linkage is Hartigan consistent

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Convergence of robust single linkage

- Robust single linkage is Hartigan consistent
- It also converges to the true tree in our metric

Convergence of robust single linkage

- Robust single linkage is Hartigan consistent
- It also converges to the true tree in our metric

Theorem

Suppose f is L-Lipschitz, compactly supported, and for any λ , $\{f \ge \lambda\}$ has finitely-many connected components Then:

- Robust single linkage ensures uniform minimality and uniform separation
- Therefore robust single linkage converges to the true cluster tree in the merge distortion metric

1. What properties ensure that an algorithm captures the true density cluster tree?

1. What properties ensure that an algorithm captures the true density cluster tree?

Hartigan consistency (allows non-minimality)

1. What properties ensure that an algorithm captures the true density cluster tree?

- Hartigan consistency (allows non-minimality)
- Minimality and separation

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency (allows non-minimality)
 - Minimality and separation
 - Minimality + separation \implies Hartigan

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency (allows non-minimality)
 - Minimality and separation
 - Minimality + separation \implies Hartigan
- 2. How "close" is a clustering to the ideal density cluster tree?

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency (allows non-minimality)
 - Minimality and separation
 - Minimality + separation \implies Hartigan
- 2. How "close" is a clustering to the ideal density cluster tree?

Merge distortion metric

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency (allows non-minimality)
 - Minimality and separation
 - Minimality + separation \implies Hartigan
- 2. How "close" is a clustering to the ideal density cluster tree?
 - Merge distortion metric
 - Convergence \iff (uniform) minimality and separation

- 1. What properties ensure that an algorithm captures the true density cluster tree?
 - Hartigan consistency (allows non-minimality)
 - Minimality and separation
 - Minimality + separation \implies Hartigan
- 2. How "close" is a clustering to the ideal density cluster tree?
 - Merge distortion metric
 - Convergence \iff (uniform) minimality and separation
- 3. Do algorithms exist which have these properties/converge to the true density cluster tree?
